

TITLE OF THE INVENTION

## 5

10

## BACKGROUND OF THE INVENTION

25

than using a captured picture, when the real space is captured by the camera. Therefore, when a virtual object is superimposed on the real space based on the position and orientation of the camera measured by the sensor, a  
5 displayed image is often shifted from a desired position.

Therefore, in the conventional technology, some methods have been suggested to improve the precision of an external parameter (position and orientation of a camera) for capturing the real space. In one of the methods, a  
10 plurality of feature points (landmarks) whose positions are known in a three-dimensional array are arranged in the real space. Then, the external parameter of the camera is corrected using an error between the actual position of a target landmark, in some landmarks captured by the camera  
15 and displayed on the display screen of the camera, and the position of the target landmark predicted based on the position and orientation of the camera at the time, acquired by a position and orientation sensor.

That is, a target landmark can be a marker such as a  
20 seal having the information of specific color or form attached to an object in the real space, or a feature point in a natural scene.

In another method, when there are a plurality of landmarks in the real space, using three (or one or two)  
25 landmarks in the vision captured by a camera, and a measurement value measured by a position and orientation sensor, a projective matrix from the real space (three-

dimensional space) to the display screen (two-dimensional plane) of the camera is calculated by a matrix operation, and an external parameter of the camera is corrected using the obtained matrix.

5           However, in the former method of the above mentioned conventional methods, the external parameter of the camera is corrected based on the target landmark. Therefore, for example, when a virtual object is superimposed on the position at a distance from a target landmark, the object  
10       can be shifted from a desired position when it is displayed. Furthermore, since a target landmark is switched and changed when the view of the camera is changed, a correction value can be largely changed when it is switched.

          On the other hand, in the latter method of the above  
15       mentioned conventional methods, an obtained projective matrix can cause an image to be mapped with incorrect orthogonality of the coordinate axis of the original coordinate system. For example, space distortion can occur depending on the detection precision of a landmark.

20           The present invention has been developed to solve the above mentioned problem, and aims at correcting the parameter indicating the position and orientation of a camera by reflecting a captured landmark.

## 25                               SUMMARY OF THE INVENTION

          To attain the purpose of the present invention, for example, a position and orientation determination

apparatus according to the present invention has the following configuration.

That is, the position and orientation determination apparatus which identifies a parameter indicating the position and orientation of capture means for capturing a picture in a real space containing a plurality of feature points whose positions are known in a three-dimensional array comprising: position and orientation measurement means for measuring the position and orientation of the capture means in a method other than using a captured picture; detection means for detecting the plurality of feature points and their positions in the two-dimensional array on the image pickup screen using the picture in the real space captured by the capture means; prediction means for predicting the positions of the feature points in the two-dimensional array on the image pickup screen based on the position and orientation of the capture means measured by the position and orientation measurement means; and correction means for correcting the parameter indicating the position and orientation of the capture means based on the positions of the feature points on the image pickup screen of the capture means obtained by the prediction means, and based on the position of the feature points obtained by the detection means. With the configuration, the parameter indicating the position and orientation of the capture means for capturing the real space is identified by the correction means correcting the parameter.

Other features and advantages of the present invention will be apparent from the following description taken in conjunction with the accompanying drawings, in which like reference characters designate the same or similar parts  
5 throughout the figures thereof.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitutes a part of the specification, illustrate  
10 embodiments of the invention and, together with the description, serve to explain the principles of the invention.

FIG. 1 shows a type of a conventional correcting method;

15 FIG. 2 shows a type of a correcting method according to a first embodiment of the present invention;

FIG. 3 shows a method of obtaining  $vx_{av}$ ;

FIG. 4 shows a type of a vector  $v4i$ ;

FIG. 5 shows a configuration of an outline of the  
20 correcting apparatus according to the first embodiment of the present invention;

FIG. 6 is a flowchart of a main process performed by the correcting apparatus according to the first embodiment of the present invention;

25 FIG. 7 is a flowchart of the correcting method by a rotation of a camera in the conventional correcting method;

FIG. 8 is a flowchart of the correcting method by translation transform of a camera in the conventional correcting method;

FIG. 9 is a flowchart of the process of <method 1>;

5        FIG. 10 is a flowchart of the process of <method 3>;  
and

FIG. 11 is a flowchart of the process of <method 5>.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

10        Preferred embodiments of the present invention will now be described in detail in accordance with the accompanying drawings.

##### [First Embodiment]

Described first is the conventional method. That is,  
15        when there are a plurality of landmarks in the real space, the method of correcting an external parameter of a camera is corrected, using an error between the actual position of a target landmark in some landmarks captured by the camera and displayed on the display screen, and the position  
20        of the target landmark predicted based on the position and orientation of the camera obtained by a position and orientation sensor. Described below is the method of using the above mentioned method for a plurality of landmarks according to an embodiment of the present invention.

25        <Conventional Method>

FIG. 1 shows a type of the above mentioned conventional method. A point A indicates the position of a landmark

predicted based on the position and orientation of a camera acquired by a position and orientation sensor. A point B indicates the actual position of the landmark. A point C indicates the position of the view of the camera. The  
5 positions indicated by the points A and B are the positions in the camera coordinate system, and the point C is the origin of the camera coordinate system. A point P indicates the position of the point A on the image pickup screen, and a point Q indicates the position of the point B on the image  
10 pickup screen. As shown in FIG. 1, the coordinates of the points P and Q are  $(X_p, Y_p)$  and  $(X_q, Y_q)$  respectively, the width and the height of the image pickup screen are  $w$  and  $h$  respectively, the focal distance (distance between the point C and the image pickup screen) of the camera is  $d$ ,  
15  $v_1$  indicates the vector from the point C to the point Q,  $v_2$  indicates the vector from the point C to the point P, and  $\theta$  indicates the angle made by the vectors  $v_1$  and  $v_2$ .

At this time, on the image pickup screen, there can be a shift (error) between the position of the landmark  
20 predicted by the position and orientation of the camera and the actual position and orientation. Two methods are suggested to correct the shift. They are: a method of changing the orientation of the camera by  $\theta$  in the direction from the point B to the point A with the position of the  
25 camera fixed (a correcting method by rotating the camera); and a method of moving the camera in parallel by the distance between the points A and B in the direction from the point

B to the point A (a correcting method by translating a camera). The two methods are described below by referring to the respective flowcharts shown in FIGS. 7 and 8.

<1. Correcting method by rotating a camera>

5 With the above mentioned settings, the elements of the vectors  $v_1$  and  $v_2$  are expressed as follows (step S701).

$$v_1 = (X_q - w/2, Y_q - h/2, -d)$$

$$v_2 = (X_p - w/2, Y_p - h/2, -d)$$

10 the respective vectors are normalized into the vector of a size of 1 (step S702). In this expression,  $|v|$  indicates the size of  $v$ .

$$vn_1 = v_1/|v_1|$$

$$vn_2 = v_2/|v_2|$$

15 When the camera is rotated, the rotation axis is orthogonal to the plane comprising the vectors  $v_1$  and  $v_2$ , and is the line passing through the view point of the camera (point C). The direction vector of the rotation axis can be obtained by calculating the outer product of the vectors  $v_1$  and  $v_2$  (actually, the value obtained by normalizing the  
20 vectors  $v_1$  and  $v_2$ ) (step S703).

$$v_x = vn_1 \times vn_2$$

$v_x$  indicates the vector of the direction of the rotation axis, and its elements are  $(l, m, n)$ . Since the rotation angle  $\theta$  is made by the vectors  $v_1$  and  $v_2$ , it can  
25 be obtained as follows (actually, it is obtained by normalizing the vectors  $v_1$  and  $v_2$ ) (step S704).

$$\theta = \arccos (vn_1 \cdot vn_2)$$

Therefore, the correction matrix  $\Delta M_c$  for correction made by rotating a camera can be computed as follows (step S705).

$$\Delta M_c = \begin{bmatrix} ll(1-\cos\theta) + \cos\theta & ml(1-\cos\theta) - n\sin\theta & nl(1-\cos\theta) + m\sin\theta & 0 \\ lm(1-\cos\theta) + n\sin\theta & mm(1-\cos\theta) + \cos\theta & nm(1-\cos\theta) - l\sin\theta & 0 \\ ln(1-\cos\theta) - m\sin\theta & mn(1-\cos\theta) + l\sin\theta & nn(1-\cos\theta) + \cos\theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

..... (1)

5        The position and orientation (external parameter) of the camera can be corrected by multiplying the matrix indicating the position and orientation of the camera (viewing transform matrix) by the correction matrix  $\Delta M_c$ . That is, the point P is displayed at the position of the point Q, and the predicted position of the landmark and the  
10        actual position matches on the image pickup screen.

#### <2. Correcting method by translating a camera>

When an error is corrected by translating a camera, as described above the position of the camera is translated  
15        in the direction from the point B to the point A by the distance between A and B. As a result, an object appearing at the position of the point P can be detected at the position of the point Q on the image pickup screen. First, the vectors  $v_1$  and  $v_2$  are obtained (step S801). A vector  $v_m$   
20        from the point P to the point Q is expressed as follows (step S802).

$$v_m = v_1 - v_2$$

Assuming that the vector from the point C to the point A is  $v_a$  (step S803), a vector  $v_3$  from the point A to the point B can be obtained as follows based on the similarity between the triangle CPQ and CAB(step S804).

5 
$$v_3 = |v_a|/|v_2| \times v_m$$

Since the shift ( $|v_3|$ ) corresponds to the shift of the position of the landmark in the camera space, the correction matrix  $\Delta M_c$  used in moving the camera in parallel can be computed as follows (step S805).

$$\Delta M_c = \begin{bmatrix} 1 & 0 & 0 & -s \\ 0 & 1 & 0 & -t \\ 0 & 0 & 1 & -u \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

10 
$$\dots\dots (2)$$

The position and orientation (external parameter) of the camera can be corrected by multiplying the matrix indicating the position and orientation of the camera by the correction matrix  $\Delta M_c$ . As a result, an object appearing at the position of the point P can be detected at the point Q on the image pickup screen.

<Method according to the present embodiment>

In the above mentioned <conventional methods>, the error above described can be reduced only around a target landmark. However, a large error can be detected around other landmarks. Therefore, according to the present embodiment, a shift is detected for all landmarks within

the view of the camera, thereby reducing an error for all landmarks by using the average error.

FIG. 2 shows a type of the correcting method according to the present embodiment. Points P1, P2, and P3 indicate the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera. Points Q1, Q2, and Q3 indicate the actual positions of the landmarks projected on the image pickup screen. According to the present embodiment, a representative point (Pav) for the points P1, P2, and P3, and a representative point Qav for the points Q1, Q2, and Q3 are generated, and the camera is rotated or translated in parallel such that the representative point Pav matches the point Qav.

<Method 1>

Method 1 is described below by referring to the flowchart shown in FIG. 9. Assuming that  $P_i$  ( $1 \leq i \leq n$ ) is a variable indicating the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera, and  $Q_i$  ( $1 \leq i \leq n$ ) is a variable indicating the actual positions of the landmarks projected on the image pickup screen, the point at the position represented by an average value of all points  $P_i$  is used as the representative point Pav (step S901).

$$P_{av} = (X_{p\_av}, Y_{p\_av})$$

$$P_i = (X_{pi}, Y_{pi})$$

$$X_{p\_av} = (X_{p1} + X_{p2} + \dots + X_{pn})/n$$

$$Y_{p\_av} = (Y_{p1} + Y_{p2} + \dots + Y_{pn})/n$$

Similarly, the point at the position indicated by the average value of all points  $Q_i$  is used as the representative point  $Q_{av}$

$$Q_{av} = (Xq_{av}, Yq_{av})$$

5  $Q_i = (Xq_i, Yq_i)$

$$Xq_{av} = (Xq_1 + Xq_2 + \dots + Xq_n)/n$$

$$Yq_{av} = (Yq_1 + Yq_2 + \dots + Yq_n)/n$$

Using the obtained representative points  $P_{av}$  and  $Q_{av}$  as the points P and Q shown in FIG. 1, the correcting method  
10 by rotating a camera as described above (refer to the flowchart shown in FIG. 7) or the correcting method by translating a camera (refer to the flowchart shown in FIG. 8) are performed (step S902) to generate the correction matrix  $\Delta Mc$ .

15 When a correction is made by translating a camera (when a process is performed according to the flowchart shown in FIG. 8), a representative point (average value) of the point (the point A shown in FIG. 1) indicating the positions of the landmarks on the image pickup screen predicted based  
20 on the position and orientation of the camera is obtained. This process is performed in step S901, and the point is used as the point A shown in FIG. 1.

#### <Method 2>

Assuming that  $P_i$  ( $1 \leq i \leq n$ ) is a variable indicating  
25 the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera, and  $Q_i$  ( $1 \leq i \leq n$ ) is a variable indicating the actual

positions of the landmarks projected on the image pickup screen, the point at the position represented by an average weighting value of all points  $P_i$  is used as the representative point  $P_{av}$ .

$$\begin{aligned}
 5 \quad & P_{av} = (X_{p\_av}, Y_{p\_av}) \\
 & P_i = (X_{pi}, Y_{pi}) \\
 & X_{p\_av} = w_1 \times X_{p1} + w_2 \times X_{p2} + \dots + w_n \times X_{pn} \\
 & Y_{p\_av} = w_1 \times Y_{p1} + w_2 \times Y_{p2} + \dots + w_n \times Y_{pn} \\
 & \text{where } w_1 + w_2 + \dots + w_n = 1
 \end{aligned}$$

10 The weighting coefficient  $w_i$  ( $1 \leq i \leq n$ ) is a coefficient value which is larger for a point closer to the center of the image pickup screen according to the present embodiment. Otherwise, for example, a value is assigned only to a target area, and the weighting coefficient  $w_i$  for  
15 the area other than the target area can be set to 0.

Similarly, the point at the position indicated by the average weighting value of all points  $Q_i$  is used as the representative point  $Q_{av}$ .

$$\begin{aligned}
 & Q_{av} = (X_{q\_av}, Y_{q\_av}) \\
 20 \quad & Q_i = (X_{qi}, Y_{qi}) \\
 & X_{q\_av} = w_1 \times X_{q1} + w_2 \times X_{q2} + \dots + w_n \times X_{qn} \\
 & Y_{q\_av} = w_1 \times Y_{q1} + w_2 \times Y_{q2} + \dots + w_n \times Y_{qn} \\
 & \text{where } w_1 + w_2 + \dots + w_n = 1
 \end{aligned}$$

Using the obtained representative points  $P_{av}$  and  $Q_{av}$   
25 as the points P and Q shown in FIG. 1, corrections are made in the above mentioned methods by rotating a camera or translating it.

The flowchart of the process in <Method 2> is obtained by changing the process of computing an average value in step S901 in the flowchart shown in FIG. 9 into the above mentioned process of computing an average weighting value.

5 When a correction is made by translating a camera, a representative point (average weighting value) of points (the point A shown in FIG. 1) indicating the positions of the landmarks predicted based on the position and orientation of the camera is obtained. This process is performed in step S901, and the obtained point is used as the point A shown in FIG. 1.

#### <Method 3>

In the methods 1 and 2, one representative point  $P_{av}$  is obtained based on the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera, and one representative point  $Q_{av}$  is obtained based on the actual positions of the landmarks projected on the image pickup screen, thereby using the correcting method based on one landmark. These methods are less costly in the calculating and more efficient than the following method, but can cause the problem that the an average value is undesired when the methods are used for two landmarks which are quite different in depth.

In <Method 3>, a correction is made by rotating a camera, not obtain a representative point, but obtain the rotation angle of the camera for each landmark and the direction vector of the rotation axis using above mentioned

correcting method by rotating a camera, and use an average of them. The <Method 3> is described below by referring to the flowchart of the process shown in FIG. 10.

Assume that  $P_i$  ( $1 \leq i \leq n$ ) is a variable indicating the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera, and  $Q_i$  ( $1 \leq i \leq n$ ) is a variable indicating the actual positions of the landmarks projected on the image pickup screen.

10 First, using each of the  $P_i$  and  $Q_i$ , the direction vector  $vx_i$  ( $1 \leq i \leq n$ ) of the rotation axis is obtained (steps S1001 to S1003) in the method similar to the above mentioned correcting method by rotating a camera, and an average value  $vx_{av}$  of all  $vx_i$  is obtained (step S1004).

15 
$$vx_{av} = (vx_1 + vx_2 + \dots + vx_n)/n$$

As shown in FIG. 3 in which the method of obtaining  $vx_{av}$  is shown, the  $vx_{av}$  is a direction vector of an average line of a rotation axis reflecting all  $P_i$  and  $Q_i$ .

Then, a rotation angle for rotation on the rotation axis (line with  $vx_{av}$  defined as a direction vector) is obtained. First, a vector  $v_{1i}$  from the point C to the point  $Q_i$  and a plane  $S_i$  passing the  $vx_{av}$  are obtained (step S1006). Then, a vector  $v_{4i}$  is obtained by projecting a vector  $v_{2i}$  from the point C to the point  $P_i$  on the plane  $S_i$  (step S1007).  
20  
25 FIG. 4 shows a type of the method of generating the vector  $v_{4i}$  computed in each of the above mentioned processes. In FIG. 4, the rotation angle for matching the point  $P_i$  with

the point Qi (by rotating the camera) is  $\theta_i$ , and the rotation angle  $\theta_i$  can be obtained by the following equations by using  $2i$  and  $v4i$  (step S1008).

$$v2ni = v2i/|v2i|$$

$$5 \quad v4ni = v4i/|v4i|$$

$$\theta_i = \arccos (v2ni \cdot v4ni)$$

Then, the average value  $\_{mean}$  of all rotation angles  $\theta_i$  is computed (step S1010).

$$\_{mean} = (\theta_1 + \theta_2 + \dots + \theta_n)/n$$

10 As a result, by rotating the camera by the rotation angle  $\_{mean}$  on the rotation axis using  $vx\_av$  as a direction vector, the camera can be rotated with reflection of all  $P_i$  and  $Q_i$  on the image pickup screen. As a result of the above mentioned computation, the correction matrix  $\Delta M_c$  can

15 be obtained using  $vx\_av$  and  $\_{mean}$  (step S1011). Assuming that  $vx\_av = (l', m', n')$ , the correction matrix  $\Delta M_c$  is expressed by the following equation.

$$\Delta M_c = \begin{bmatrix} l'l'(1-\cos\theta_{mean})+\cos\theta_{mean} & m'l'(1-\cos\theta_{mean})-n'\sin\theta_{mean} & n'l'(1-\cos\theta_{mean})+m'\sin\theta_{mean} & 0 \\ l'm'(1-\cos\theta_{mean})+n'\sin\theta_{mean} & m'm'(1-\cos\theta_{mean})+\cos\theta_{mean} & n'm'(1-\cos\theta_{mean})-l'\sin\theta_{mean} & 0 \\ l'n'(1-\cos\theta_{mean})-m'\sin\theta_{mean} & m'n'(1-\cos\theta_{mean})+l'\sin\theta_{mean} & n'n'(1-\cos\theta_{mean})+\cos\theta_{mean} & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

..... (3)

20 The position and orientation (external parameter) of the camera can be corrected by multiplying the matrix indicating the position and orientation of the camera by the correction matrix  $\Delta M_c$ . That is, each point  $P_i$  on the

image pickup screen is displayed near each point  $Q_i$  on an average, and the predicted position of the landmark matches on an average with the actual position of the landmark. In this method, a correction matrix can be generated with the position information about all landmarks on the image pickup screen reflected, and the orthogonality of the coordinate system transformed by the generated correction matrix can be maintained.

#### <Method 4>

10 In the method 3, when  $vx\_av$  and  $\_mean$  are obtained, an average value is obtained for each of  $vx_i$  and  $\theta_i$ . However, in <Method 4>, it is obtained by computing an average weighting value. That is, it is computed by the following equation.

15 
$$vx\_av = w_1 \times vx_1 + w_2 \times vx_2 + \dots + w_n \times vx_n$$
$$\_mean = w_1 \times \theta_1 + w_2 \times \theta_2 + \dots + w_n \times \theta_n$$
where  $w_1 + w_2 + \dots + w_n = 1$

Other steps are similar to those in the method 3. The flowchart of the process in the <Method 4> is obtained by changing the average computation in steps S1004 and S1010 in the flowchart shown in FIG. 10 into the above mentioned average weighting computation.

#### <Method 5>

25 In the methods 1 and 2, one representative point  $P_{av}$  is obtained based on the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera, and one representative point  $Q_{av}$

is obtained based on the actual positions of the landmarks projected on the image pickup screen, thereby using the correcting method based on one landmark. In <Method 5>, a correcting method by moving a camera in parallel is suggested, not obtain a representative point, but obtain a translation transform element of a camera for each landmark in the above mentioned correcting method by translating the camera, and the obtained element is used on an average. FIG. 11 is a flowchart of the process of <Method 5>.

Assume that  $P_i$  ( $1 \leq i \leq n$ ) is a variable indicating the positions of the landmarks on the image pickup screen predicted based on the position and orientation of the camera, and  $Q_i$  ( $1 \leq i \leq n$ ) is a variable indicating the actual positions of the landmarks projected on the image pickup screen. First, using the above mentioned correcting method by translating a camera, the vector  $v_{3i} = (s_i, t_i, u_i)$  is obtained for each of  $P_i$  and  $Q_i$  (step S1101 to S1103). Then, an average value of the vector  $v_{3i}$  is obtained for each of  $P_i$  and  $Q_i$  (step S1104).

$$s_{\text{mean}} = (s_1 + s_2 + \dots + s_n)/n$$

$$t_{\text{mean}} = (t_1 + t_2 + \dots + t_n)/n$$

$$u_{\text{mean}} = (u_1 + u_2 + \dots + u_n)/n$$

Using  $s_{\text{mean}}$ ,  $t_{\text{mean}}$ , and  $u_{\text{mean}}$ , a correction matrix is obtained as follows (step S1105).

$$\Delta M_c = \begin{bmatrix} 1 & 0 & 0 & -s_{mean} \\ 0 & 1 & 0 & -t_{mean} \\ 0 & 0 & 1 & -u_{mean} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

..... (4)

<Method 6>

In the method 5, when the translation transform element of a camera is obtained, an average value of the vector v3i is used. However, in method 6, an average weighting value is used. The average weighting value is obtained by the following equations

$$S_{w\_mean} = w_1 \times s_1 + w_2 \times s_2 + \dots + w_n \times s_n$$

$$t_{w\_mean} = w_1 \times t_1 + w_2 \times t_2 + \dots + w_n \times t_n$$

$$u_{w\_mean} = w_1 \times u_1 + w_2 \times u_2 + \dots + w_n \times u_n$$

where  $w_1 + w_2 + \dots + w_n = 1$ .

A correction matrix is obtained as follows using  $S_{w\_mean}$ ,  $t_{w\_mean}$ , and  $u_{w\_mean}$ .

$$\Delta M_c = \begin{bmatrix} 1 & 0 & 0 & -S_{w\_mean} \\ 0 & 1 & 0 & -t_{w\_mean} \\ 0 & 0 & 1 & -u_{w\_mean} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

..... (5)

The flowchart of the process in the <Method 6> is obtained by changing the average computation in steps S1104

in the flowchart shown in FIG. 11 into the above mentioned average weighting computation.

<Method 7>

In any of the methods 1 to 6, a correction matrix is  
5 computed by either rotating a camera or translating it, and  
a correction matrix having elements of both rotation and  
translation cannot be obtained. Then, in method 7, the  
computation of a correction matrix by rotation and the  
computation of a correction matrix by translation are  
10 performed to compute a correction matrix by combining the  
above mentioned matrices.

First, a correction matrix by rotation is obtained in  
any method above mentioned. Then, using the obtained  
correction matrix, the position and orientation of the  
15 camera is corrected, and the position of the landmark on  
the image pickup screen is obtained. Based on the obtained  
predicted position, a new correction matrix by translation  
is obtained in any method. In this method, a correction  
can be first made by translation, and then a correction can  
20 be made by rotation.

In addition, without making corrections once by  
rotation and once by translation as described above, the  
processes can be alternately repeated.

Furthermore, when they are repeatedly performed, the  
25 numbers of times they are performed can be determined not  
only predetermined times, but also based on the error  
between the position of a landmark on the image pickup

screen predicted from the position and orientation of the camera and the position obtained by actually capturing the position. The method can be used by determining whether or not the error indicates a value equal to or smaller than a predetermined threshold, by determining whether or not the amount of a change in the error is equal to or smaller than a predetermined value, or by combining the determination above.

#### <Correcting Apparatus>

10 FIG. 5 shows the rough configuration of the correcting apparatus for performing the above mentioned correcting processes according to the embodiment of the present invention. Reference numeral 501 denotes a head mounted display (hereinafter referred to as an HMD). The HMD 501  
15 comprises a three-dimensional position and orientation sensor 501a for outputting a signal based on the position and orientation of the HMD 501 in the three-dimensional space to a position and orientation measurement unit 502 described later, a camera 501b for capturing an image of  
20 an object in the real space, and a display unit 501c for providing a picture for a user who has the HMD 501 on his or her head. The HMD 501 according to the present embodiment is of a video see-through type. The position and orientation of the HMD 501 refers to the position and  
25 orientation of the camera 501b.

The position and orientation measurement unit 502 generates a matrix (viewing transform matrix) indicating

the position and orientation of the HMD 501 based on the signal output from the three-dimensional position and orientation sensor 501a. Reference numeral 503 denotes a landmark detection unit. The landmark detection unit 503  
5 detects a landmark from a picture captured by the camera 501b. It also detects the position of the landmark. The method of detecting them is not specified here. However, for example, a marker of a specified color is used as a landmark. Then, the specified color is detected in the  
10 picture captured by the camera 501b. As a result, the landmark and its position can be detected in the picture.

Reference numeral 504 denotes a position and orientation correction unit. The position and orientation correction unit 504 computes a correction matrix using any  
15 of the above mentioned methods (any method in <Method 1> to <Method 7>) according to the position information about each landmark output from the landmark detection unit 503. Then, the matrix indicating the position and orientation of the HMD 501 output from the position and orientation  
20 measurement unit 502 is multiplied by the computed matrix. As a result, the position and orientation (external parameter) of the HMD 501 can be corrected. Reference numeral 505 denotes an image generation unit. The image generation unit 505 generates a picture of a virtual object  
25 based on the matrix corrected by the position and orientation correction unit 504, and augmented the picture and the picture in the real space input from the camera 501b.

As a result, a picture (image) of augmented reality can be generated. It is assumed that the data relating to the virtual object is stored in the external memory. The generated image is output to the display unit 501c.

5        FIG. 6 is a flowchart of the processes mainly performed by the correcting apparatus with the above mentioned configuration. Since each of the processes is described above, the detailed explanation is omitted here. The program code according to the flowchart shown in FIG. 6 is  
10       stored in the memory such as RAM, ROM, etc. stored in the correcting apparatus according to the present embodiment, not shown in the attached drawings, but read and executed by the CPU also not shown in the attached drawings.

First, a signal indicating the position and  
15       orientation of the HMD 501 is input from the three-dimensional position and orientation sensor 501a to the position and orientation measurement unit 502 (step S601), and the position and orientation measurement unit 502 generates a viewing transform matrix indicating the  
20       position and orientation of the HMD 501 according to the input signal (step S602). On the other hand, a picture in the real space is captured by the camera 501b (step S603). The captured picture is input to the landmark detection unit 503, and the landmark and its position are detected (step  
25       S604). The position and orientation correction unit 504 generates a correction matrix  $\Delta M_c$  according to the

above-mentioned methods (any of <Method 1> to <Method 7>) based on the detected position of the landmark (step S605).

Using the viewing transform matrix indicating the position and orientation of the HMD 501 and the correction matrix  $\Delta Mc$  generated in the processes above, the position and orientation correction unit 504 corrects the position and orientation of the HMD 501 (step S606). According to the external parameter indicating the corrected position and orientation of the HMD 501, the image generation unit 505 generates a picture of a virtual object, and generates a picture of augmented reality (step S607). Then, the generated picture of augmented reality is output to a display unit 101a, (step S608), and displayed on the display unit 101a (step S609).

As described above, the correcting apparatus and method according to the present embodiment can correct the position and orientation of the HMD 501 although the measurement precision of the position and orientation of the HMD 501 obtained by the three-dimensional position and orientation sensor 501a is not satisfactory.

In addition, a position error can be prevented although a picture in the real space captured by the camera 502b in the HMD 501 is augmented with a picture of a virtual object generated based on the position and orientation of the HMD 501.

In addition, since the position and orientation of the HMD 501 are corrected using all landmarks on the image

pickup screen, a large change in a correction value is not made by changing the view of the camera.

Note that the present invention may be applied to either a system constituted by a plurality of devices (e.g.,  
5 a host computer, an interface device, a reader, a printer, and the like), or an apparatus consisting of a single equipment (e.g., a copying the machine, a facsimile apparatus, or the like).

The objects of the present invention are also by  
10 supplying a storage medium, which records a program code of a software program that can implement the functions of the above mentioned embodiments to the system or apparatus, and reading output and executing the program code stored in the storage medium by a computer (or a CPU or MPU) of  
15 the system or apparatus.

In this case, the program code itself read out from the storage medium implements the functions of the above mentioned embodiments, and the storage medium which stores the program code constitutes the present invention.

20 As the storage medium for supplying the program code, for example, a floppy disk, hard disk, optical disk, magneto-optical disk, CD-ROM, CD-R, magnetic tape, nonvolatile memory card, ROM, and the like may be used.

The functions of the above mentioned embodiments may  
25 be implemented not only by executing the readout program code by the computer but also by some or all of actual processing operations executed by an OS (operating system)

running on the computer on the basis of an instruction of the program code.

The present invention includes a product, e.g., a printout, obtained by the image processing method of the present invention.

Furthermore, the present invention also includes a case where, after the program codes read from the storage medium are written in a function expansion card which is inserted into the computer or in a memory provided in a function expansion unit which is connected to the computer, CPU or the like contained in the function expansion card or unit performs a part or entire process in accordance with designations of the program codes and realizes functions of the above embodiments.

When the present invention is applied to the above mentioned storage medium, the storage medium stores a program code corresponding to at least one flowchart in the flowcharts shown in FIG. 6 as described above and described in <Method 1> to <Method 6>.

As many apparently widely different embodiments of the present invention can be made without departing from the spirit and scope thereof, it is to be understood that the invention is not limited to the specific embodiments thereof except as defined in the appended claims.
